INTRODUCTION

TRENDS IN NUMBER AND CASELOAD OF PRIVATE PSYCHIATRIC HOSPITALS

Private psychiatric hospitals (i.e., nongovernmental hospitals used exclusively for psychiatric patients) which are operated on either a not-forprofit or a for-profit basis have increased in number from 151 in 1968 to 180 in 1975 (table A). In the same time interval the number of annual additions to these hospitals increased from 89,138 to 119,071, an increase of 34 percent, while the number of inpatients at year end increased from 10,454 to 11,496 (10 percent) (table B).

As shown in table B, the increase in the number of hospitals, additions, and inpatients between 1968 and 1974 was not uniform. For example, in the interval 1968-70 there were approximately 150 private psychiatric hospitals averaging around 90,000 additions per year and about 10,700 inpatients (Taube and Redick 1975). However, in the interval 1970-72, the number of hospitals increased by 27 with consequent increases of 14,000 annual additions and about 500 inpatients (table B).

The growth in the number of hospitals in the interval 1968-72 was due largely to new for-profit corporation hospitals that opened (table A). For-profit hospitals operated by corporations increased 55 percent between 1968-72, while for-profit hospitals operated by individuals or partnerships decreased by 30 percent and the number of not-for-profit hospitals operated by churches decreased by 24 percent (table A).

SOURCES OF DATA AND EXTENT OF NONRESPONSE

The data in this report are based on information collected from two sources: the Inventory of Mental Health Facilities (Inventory)^a and the

special Supplement of Physician Staff (Supplement), both of which were conducted in January 1975 by the National Institute of Mental Health (NIMH) in cooperation with State mental health authorities and the National Association of Private Psychiatric Hospitals (NAPPH). The Supplement was mailed to all psychiatric (including private) hospitals as a one-time addendum to the Inventory for the purpose of studying the demographic and selected professional credentials of psychiatrists and other physicians employed in the hospitals.

In the January 1975 Inventory, the overall response rate for private psychiatric hospitals was 93 percent. However, of those hospitals submitting a questionnaire, the number answering a given question (e.g., expenditures, number employed) varied. An analysis of nonrespondents to particular items is given in appendix III. Data derived from the Inventory, which are presented in this report, have been adjusted to include estimates for hospitals that did not answer a particular question.

The rationale for including estimates for facilities that did not respond to either a particular question or to the entire Inventory was based on two factors: (1) the overall response rate and the response rate for most items were relatively high and (2) since nonresponse for most given items varied relatively little by size of the hospital (based on number of beds), geo-

^a Annual and biennial inventories of facilities, the purpose of which is to provide basic data on each mental health facility in

the country relating to its caseload, staffing and expenditure patterns, and services provided. Psychiatric hospitals (including private psychiatric hospitals) and community mental health centers are surveyed annually. Other facilities such as day/night facilities, psychiatric outpatient clinics, general hospital psychiatric services, and residential treatment centers for emotionally disturbed children are surveyed biennially.

b The supplemental form requested the hospitals to list all physicians who were employed in the hospitals during a sample week in January 1975 and to provide information on their age and sex, hours worked, licensure status, specialty (ABPN) and ECFMG certification, type of position, citizenship, and country in which they received their medical degree.

graphic region, and hospital control, there is little reason to believe that nonresponse would introduce bias in the inflated estimate.

Information was obtained on 1,324 physicians on the supplement. This represents 87 percent of the 1,521 physicians employed in private psychiatric hospitals during the sample week. Data derived from the Supplement (see tables O-U and 9-10) are based on the 1,324 physicians and have not been adjusted to include estimates for the 197 estimated physicians which were not reported on the Supplement.

A total of 180 private psychiatric hospitals (excluding those in Puerto Rico) were identified on the Inventory. Because of slight differences

in classification as well as differences in the point in time when the lists were compiled, both the number and distribution of hospitals differ slightly from a list compiled by the National Association of Private Psychiatric Hospitals (NAPPH) of its member hospitals. A discussion of some of the reasons for differences in the two lists is given in appendix I.

Definitions of terms are presented in appendix II and special symbols used in the tables are shown on page ii at the beginning of this report. Since many of these definitions and symbols have specialized meanings in this report, familiarity with them will aid in the interpretation of

the data.

CHARACTERISTICS OF PRIVATE PSYCHIATRIC HOSPITALS

NUMBER OF FACILITIES AND BEDS

As of January 1975 there were 180 private psychiatric hospitals in the United States which maintained a total of 15,908 beds. The median number of beds per hospital was 66 (table C). There were 8 private psychiatric hospital beds per 100,000 United States civilian resident population (table D).

Nearly two-thirds of the hospitals (117 of 180) were operated either by corporations, individuals, or partnerships on a for-profit basis; the other one-third (63 of 180) were operated by church, foundation, and other not-for-profit groups (table C). However, the for-profit hospitals contained only 57 percent of the beds. The for-profit hospitals had a median of 60 beds as compared with a median of 82 beds for the not-for-profit group.

The distribution of the 180 private psychiatric hospitals is shown by State and geographic region in table 1. Fifteen States had no private psychiatric hospitals and another 11 had only one hospital. California had the most hospitals (27) and the most beds (2,065), followed by New York with 14 hospitals and 1,230 beds. Jointly these two States accounted for 23 percent of all private psychiatric hospitals and 21 percent of all beds.

Region III had both the most hospitals and the most beds; the fewest hospitals and beds were in Region X (tables 1 and D). Region I (New England) had the most beds in private psychiatric hospitals per 100,000 United States civilian resident population (17), followed by Region III (13) (table D).

In addition to "inpatient treatment" which was provided by all private psychiatric hospitals, other service modes and the percent of the hospitals which maintained each type of mode included day treatment (43 percent), outpatient treatment (34 percent), halfway house (9 percent), and emergency services (25 percent). The availability of these service modes showed wide variation according to hospital control. A greater proportion of not-for-profit as compared with for-profit hospitals maintained each of the service modes shown in table 2. Over half of the not-for-profit hospitals maintained outpatient modes as compared with only one-quarter of the for-profit hospitals; 17 percent of the not-forprofit hospitals and halfway houses as compared with only 4 percent of the for-profit group.

One possible reason for this is that fewer forprofit hospitals qualify for reimbursement of day treatment and outpatient services by thirdparty insurance payers and have little financial incentive to maintain these service modes.

RESTRICTIONS REGARDING ADMISSION

On the NIMH Inventory, the private psychiatric hospitals were asked specifically for diagnostic and age restrictions regarding admission to inpatient and other service modes. Restrictions

regarding admission to inpatient, outpatient, and day treatment service modes are summarized for age and diagnostic restrictions in tables 3 and 4 respectively.

By far the group most frequently specified as being excluded from each of the three service modes was mental retardates who were excluded from 46 percent of inpatient modes, 44 percent of the day treatment modes, and 38 percent of the outpatient modes (table 3). In addition, there were substantial differences in the exclusion of mental retardates by hospital control. Whereas 45 percent of the outpatient modes in for-profit hospitals excluded mental retardates, only 31 percent of the outpatient modes in not-for-profit hospitals had this policy. On the other hand, 52 percent of the inpatient modes in not-for-profit

hospitals did not admit mental retardates as compared with 42 percent in the for-profit hospitals.

Over half (51 percent) of the outpatient modes stated that they served persons of all ages as compared with 34 percent of the inpatient modes and 28 percent of the day treatment modes (table 4). For each of the three service modes, over 90 percent stated that they had no maximum age, i.e., they either had a minimum age but no maximum age or they admitted persons of all ages (table 4).

Two to three percent of each of the three service modes were specifically for children, i.e., they specified a maximum age of 18 years and under. All of the hospitals for children except one were under not-for-profit auspices.

CASELOAD AND UTILIZATION

INPATIENT TREATMENT MODES

At the end of 1974 there were 11,496 inpatients in private psychiatric hospitals, an increase of 3.5 percent over the 11,109 inpatients at the beginning of the year (table E). Similar proportionate increases occurred in the not-forprofit group which increased from 5,331 to 5,503 (3.2 percent) and in the for-profit group which increased from 5,778 to 5,993 (3.7 percent). The number of patients under care during 1974 c numbered 130,180 of which 78,433 (60.2 percent) were in for-profit hospitals and 51,747 (39.8 percent) were in not-for-profit hospitals.

In comparison with for-profit psychiatric hospitals, not-for-profit hospitals on the average had more beds, a higher average daily census, and higher rate of occupancy (table F). However, the rate of turnover of patients was much greater in for-profit psychiatric hospitals. For example,

OUTPATIENT AND OTHER SERVICE MODES

Although private psychiatric hospitals, in general, put the most emphasis on the provision of treatment in inpatient modes, some patients are also served in outpatient treatment and in other service modes. Table G shows the total additions and average additions per hospital to three noninpatient service modes of private psychiatric hospitals—outpatient treatment, day treatment, and halfway house modes—by hospital control.

Of the three noninpatient modes, outpatient service modes had the largest number of additions, an estimated total of nearly 23,000 or an average 374 additions per hospital for the 61 hospitals that reported having this service mode (tables 2 and G). Not-for-profit hospitals had 17,504 outpatient additions or more than three times the 5,336 outpatient additions in for-profit hospitals.

for-profit psychiatric hospitals had 1,234 additions per 100 average inpatients as compared with a ratio of 857 for not-for-profit hospitals. This higher rate of turnover in for-profit hospitals prevailed in all bed size classes and is due in part to the shorter average lengths of stay experienced by patients in for-profit as compared with not-for-profit hospitals (see table F).

of inpatients in private psychiatric hospitals at the beginning of year plus the total additions (see definition in appendix II) to these facilities during the year. In this paper it is the closest approximation to obtaining an unduplicated count of persons seen during the year in inpatient modes of private psychiatric hospitals. However, in calculating this measure, two types of duplication can occur: (1) the same person may be admitted more than once to a particular facility during the year and is counted each time he or she is admitted, or (2) the same person may be admitted to two or more different facilities during the year and each admission to each facility is counted.

Table C. Number and percent distribution of private psychiatric hospitals and beds and median number of beds per group by hospital control and size (based on number of beds): United States, January 1975

Source (1972 data): National Institute of Mental Health, 1974. Staffing of Mental Health Facilities, 1972. DHEW Publication No. (ADM) 74-28. Washington, D.C.: U.S. Government Printing Office.

Source (1975 data): Unpublished data from Division of Biometry and Epidemiology, NIMH.

Day treatment additions numbered 2,881 or an average of 37 additions per hospital program for the 77 hospitals with day treatment programs. The average number of day treatment additions per hospital was 53 additions in the 29 not-forprofit hospitals as compared with 28 additions in the 48 for-profit hospitals which maintained a day treatment mode (table G).

Relatively few private psychiatric hospitals operated halfway houses. The 16 private psychiatric hospitals that operated halfway houses had 297 beds, a total of 19 beds per hospital for the 16 hospitals that reported having this service.

STAFFING PATTERNS

Beginning in 1968, the National Institute of Mental Health in its annual Inventory has collected information on the number of staff and hours worked in private psychiatric hospitals during a sample week in January. Data derived from the information collected are available in a number of NIMH reports (viz, NIMH 1970, NIMH 1972, NIMH 1974, NIMH 1976).

The information is available for specific staff disciplines by employment status, i.e., whether persons are employed full time (35 hours or more weekly), part time (less than 35 hours weekly), or as trainees, residents, or interns. These data enable trends in the number of full-time equivalent staff (FTE) and staff distribution by discipline to be examined over time (see tables H and I) and also permit a detailed analysis of staffing patterns in all private psychiatric hospitals in January 1975. These two topics are discussed in the first two sections of this chapter.

In January 1975, NIMH also conducted a onetime special Supplement on Physician Staff (see page 1 and footnote^b) in private psychiatric hospitals, the purpose of which was to study professional credentials, licensure status, and demographic characteristics of American (including Canadian) and foreign medical graduates. This topic is discussed in the third section of this chapter.

TRENDS BETWEEN 1972-75

Between 1972 and 1975 the estimated number of full-time equivalent (FTE) staff employed in private psychiatric hospitals rose from 21,504 to 24,142, an increase of 12 percent (table H). With the exception of FTE psychiatrists and FTE administrative and maintenance staff, all disciplines showed increases in FTE staff ranging from 10 percent for registered nurses to 148 percent for FTE "other professionals" which in-

clude vocational rehabilitation counselors, school teachers, activity therapists as well as other health and mental health professionals. The reason for the large increase in this staff discipline group was not readily apparent. However, by comparison, State and county mental hospitals also showed a relatively large proportional increase in "other professionals" between 1972 and 1975 (47 percent).

Among the two groups which showed decreases in number of FTE staff, FTE psychiatrists^d which declined from 1,067 to 984 (8 percent) had the sharpest decrease (table H).

Most of the increase in the total FTE staff and in the FTE professional patient care staff between 1972 and 1975 was due primarily to an increase in the FTE staffs of hospitals in operation at both time periods rather than to the opening of new hospitals between the two periods. As given below, the 122 private psychiatric hospitals which were in operation and reported data for both 1972 and 1975 showed an increase of 12 percent and 33 percent for total FTE staff and FTE professional patient care staff respectively. These increases are in line with the estimated increases for all private psychiatric hospitals between 1972 and 1975 (table H).

The relatively sharp increase in the number of FTE professional patient care staff accompanied by the moderate decrease in the number of FTE administrative and maintenance staff between 1972 and 1975 resulted in a different staff composition in 1975 as compared with 1972 (table I). Professional patient care staff comprised 33 percent of total FTE staff in 1975 as

d It should be noted that FTE's and other staff data shown in this section reflect hours worked by psychiatrists and other physicians on the staff of the hospitals. Many other psychiatrists have staff privileges and visit patients in the hospital. However, these FTE's are not included in the staff tables.

| | FTE's 1972 (122 hospitals) | FTE's 1975 (122 hospitals) | Percent change 1972-75 |
|--|----------------------------------|----------------------------------|---------------------------|
| All staff | 17,356 | 19,437 | 12.0 |
| Patient care staff Professional patient | 9,175 | 11,652 | 27.0 |
| care staff | 4,813 | 6,422 | 33.4 |
| Other patient care staff: | 4,362 | 5,230 | 19.9 |
| All other staff | 8,181 | 7,785 | -4.8 |

compared with 27 percent in 1972. Other patient care staff rose slightly from 26 percent of the total in 1972 to 27 percent in 1975, and FTE administrative and maintenance staff declined from 47 percent of the total in 1972 to 39 percent of the total in 1975 (table I).

STAFFING OF PRIVATE PSYCHIATRIC HOSPITALS – 1975

Number and Distribution of Staff—Private psychiatric hospitals employed an estimated 27,734 persons during a sample week in January 1975, of 75 percent were employed whom full time, 21 percent part time, and 4 percent as trainees, residents, or interns (tables 5 and 6). In terms of broad staff categories, professional patient-care staff comprised 36 percent of staff positions and 33 percent of staff hours, other patient-care staff comprised 26 percent of staff positions and 27 percent of staff hours, and all other staff (administrative and maintenance) comprised 38 percent of staff positions and 39 percent of staff hours (table 7).

Table 8 shows the number and percent distribution of full-time equivalent staff (FTE's) for selected professional staff disciplines. A summary of some of the findings based on data in tables 7 and 8 is as follows:

• More registered nurses were employed in private psychiatric hospitals than any other "professionals" engaged in patient care. Of the 24,142 FTE's in private psychiatric hospitals, 2,902 (12 percent) were registered nurses. However, within the professional patient care group, RN's comprised 2,902 of 8,033 total FTE's (36 percent).

- The number of FTE psychiatrists (see footnoted) outnumbered both the FTE social workers and the FTE psychologists. FTE psychiatrists comprised 4 percent of total FTE staff and 12 percent of the "professional patient care staff."
- For-profit and not-for-profit psychiatric hospitals differed, particularly in the distribution of specialized mental health personnel such as FTE psychiatrists, psychologists, and social workers, in comparison with forprofit hospitals. For example, not-for-profit hospitals had a higher proportion of FTE psychiatrists, physicians other than psychiatrists, psychologists, and social workers than did for-profit hospitals (table 8). In the case of psychiatrists and other physicians this is due to the greater use of "open staff" physicians in the for-profit hospitals (see "Staffing Arrangements of Physicians").

An indication that the staff composition in private psychiatric hospitals has experienced relatively little change in recent years is that the above results are consistent with those obtained in 1970 (NIMH 1972).

Staffing Arrangements of Physicians—In previous reports (viz NIMH 1972, NIMH 1974, NIMH 1976) NIMH has presented data which show the number of FTE staff per 100 average resident inpatients. The computation of this ratio for physicians assumes that most of the patients are under the care of physicians who are on the staffs of the hospitals and who are paid salaries by the hospital for other than work on a medical committee. A recent article in the Newsletter of the National Association of Private Psychiatric Hospitals (NAPPH 1976) reported that a substantial number of private psychiatric

hospitals had open medical staffs.^e If substantial numbers of inpatients in private psychiatric hospitals are under the care of open staff physicians, the FTE staff to resident patient ratios for physicians (psychiatrists and other physicians) would be spuriously low since only salaried physicians on the staffs of the hospitals are included in the numerator of the ratio, while all inpatients comprise the denominator.

In order to determine the proportion of inpatients under the care of salaried physicians and also to verify the number of salaried physicians reported on the January 1975 Inventory of Mental Health Facilities and ultimately to check the validity of presenting FTE staff to resident patient ratios, NIMH recontacted all private psychiatric hospitals in July 1976. Information was obtained from 157 (87 percent) of the 180 facilities classified as private psychiatric hospitals by NIMH. The results of some information from this followup study are shown in tables I through

Nearly 53 percent of the inpatients in the 157 hospitals were under the care of nonsalaried (open staff) physicians. By ownership type, 61 percent of the inpatients in for-profit hospitals and 44 percent of the inpatients in not-for-profit hospitals were under the care of nonsalaried physicians (table J). For this reason, NIMH has not calculated any staff-to-resident-patient ratios. Other highlights of data contained in tables

- Proportionately, over 1½ times as many not-for-profit (36 percent) as compared with for-profit hospitals (24 percent) had closed medical staffs. However, a higher proportion of for-profit hospitals had both open and mixed staffs as compared with not-for-profit hospitals (table K).
- There appears to be little relationship between size of hospital (based on number of beds) and type of hospital staffing arrangement, with the exception being that the proportion of hospitals with mixed staff

J-N are as follows:

e Three basic types of staff arrangements—open staff, closed staff, and mixed staff-are found in private psychiatric hospitals. In open staff hospitals, all of the physicians have staff privileges but are not paid salaries by the hospital for the care of patients. In closed staff hospitals, all of the physicians are on the staffs of the hospitals and are paid salaries directly by the hospital for the care of the patients. A mixed staff hospital is one which has combinations of open and closed staffing arrangements.

- was progressively larger as size of hospital increased (table K).
- Nearly 39 percent of the inpatients were in hospitals which had open staffs, 35 percent in hospitals with closed staffs, and 26 percent in hospitals with mixed staffs (table L). The largest proportion of inpatients in for-profit hospitals were in open staff hospitals (42 percent); the largest proportion of inpatients in not-for-profit hospitals were in closed staff hospitals (43 percent) (table L).
- A larger proportion of not-for-profit (78 percent) as compared with for-profit psychiatric hospitals (69 percent) had a paid medical director. Also a larger proportion of the largest hospitals (in terms of both inpatient beds and numbers of physicians which were salaried by the hospital) had a paid medical director (tables M and N). These results were consistent with those found in the NAPPH survey (NAPPH 1976).

DEMOGRAPHIC CHARACTERISTICS AND PROFESSIONAL CREDENTIALS OF PHYSICIANS

The Special Supplement on Physician Staff (see page 1) to the Inventory of Mental Health Facilities conducted in January 1975 provides much useful information on the characteristics of physicians f employed and salaried by private psychiatric hospitals. Data derived from the supplement are shown in tables O-U, 9 and 10.

Information was obtained on 1,324 physicians. This represents 87 percent of the estimated total of 1,521 physicians on the staffs of private psychiatric hospitals as of January 1975.

Of the 1,324 physicians 81.3 percent were graduates of American (including Puerto Rican) and Canadian medical schools and 18.7 percent were graduates of medical schools in all other countries (table P). This contrasts sharply with State mental hospitals in which approximately half of the physicians were graduates of schools

f Includes MD's or DO's who were sick or on vacation during the sample week. Includes consultants if they work on a regular basis. Includes MD's or DO's who regularly work in the hospital, but who may be paid by another agency. Excludes physicians who have privileges to see private patients unless they are also employed as staff psychiatrists, other staff physicians or residents.

Table I. Percent distribution of full-time equivalent staff of private psychiatric hospitals by selected staff categories:

^{1/} Based on reports from 157 hospitals with no adjustments for nonresponse.

outside the United States and Canada (NIMH May 1976).

In all further discussion, graduates of American and Canadian medical schools are grouped together because of similarities of education, medical school accreditation, and licensure requirements and are referred to throughout this report as AMG's. All other medical graduates are grouped together and are called foreign medical graduates (FMG's).

Age, Sex, and Citizenship—Nearly 88 percent of the physicians were male, over one-third were 45 years of age and over, and 91 percent were U.S. citizens (table 9). As a group, AMG's differ markedly from FMG's in their distribution by age, sex, citizenship, and in terms of the position in which they were employed in private psychiatric hospitals (table 9). For example, 16 percent of the FMG's were female as compared with 11 percent of the AMG's; 75 percent of the FMG's were 35 years and older as compared with 66 percent of the AMG's; and 42 percent of the FMG's were citizens of a country other than the United States as compared with only 1 percent of the AMG's.

The sex and age differentials were especially apparent among residents. Among FMG's employed as residents, 28 percent were female as compared with only 19 percent of the AMG's. Only 73 percent of the FMG residents were less than 35 years as compared with 90 percent of the AMG's.

AMG's and FMG's are similarly distributed with regard to type of position in which employed as residents in the AMG group (20 percent) as compared with the FMG group (24 percent) (table O).

Geographic Area of World in Which Medical Degree Earned—The FMG's received their medical degrees in 47 countries (exclusive of the United States and Canada). In contrast to the Far East which produced the predominance of FMG's in State mental hospitals (NIMH May 1976), Europe accounted for over half the FMG's in private psychiatric hospitals or three times the number in any of the other geographical areas of the world (table P). The Far East and Latin America provided 18 percent and 17 percent respectively and the Near and Middle East (12 percent) (table P).

By country, Italy provided the most FMG's, followed by Germany, Switzerland, the United Kingdom, the Philippines and India (table Q).

Licensure and Professional Credentials—FMG's are used more extensively in full-time than in part-time positions. By type of position there is slight variation in the proportion of FMG's among all medical graduates, according to whether they are employed full or part time. Among all physicians the proportion of FMG's ranges from 16 percent of "other staff physicians" to 22 percent of the residents. Among full-time positions the proportion of FMG's ranged from 15 percent of "other staff physicians" to 24 percent of the residents (table R).

Overall only 83 percent of the FMG's held an unlimited license to practice in the State in which they are working compared with 94 percent of the AMG's (tables S and T). In comparison with private psychiatric hospitals virtually the same proportion of AMG's in State mental hospitals had unlimited licenses (93 percent), but a substantially lower proportion of FMG's had unlimited licenses (58 percent) (NIMH May 1976).

The possession of an unlimited license was strongly related to the type of position in which the physician was employed. Among both AMG's and FMG's nearly all of the staff psychiatrists and other staff physicians had unlimited licenses. Among residents, the proportion with unlimited licenses was substantially lower among both AMG's (78 percent) and FMG's (45 percent). Licensure was also closely related to whether or not the physician was a citizen of the United States. Overall, 143 out of 247 FMG's (58 percent) were United States citizens and 92 percent of these held unlimited licenses (table T). By contrast only 70 percent of the non-United States citizen FMG's were fully licensed. Among FMG's in State mental hospitals only 45 percent were United States citizens and 43 percent of these had an unlimited license. (NIMH May 1976).

Before an FMG is eligible for appointment as an intern or resident in any AMA approved program for graduate medical training, he or she must pass an examination administered by the

g The question specifically asked on the Supplemental Form was whether the physician had an unlimited (full) license in that State in which he or she was employed. Thus, some physicians who were licensed in a State other than the one in which they were employed were counted as being unlicensed. For this reason, the number of physicians who have an unlimited (full) license in any State is undercounted by an unknown amount in this report.

Educational Council for Foreign Medical Graduates (ECFMG). This explains why 98 percent of the residents either passed the ECFMG or the ECFMG exam was not required, as compared with only 80 percent of the staff psychiatrists and 95 percent of the other physicians (table 10). Information was also obtained for each physician regarding his or her certification by the American Board of Psychiatry and Neurology (ABPN). The responses were analyzed only for

(ABPN). The responses were analyzed only for those employed as staff psychiatrists and, again,

there was a clear difference in the proportions of AMG's and FMG's who passed. Only 40 percent of the FMG psychiatrists were certified by the ABPN as compared with 53 percent of the AMG psychiatrists. Within both the AMG and FMG groups, slightly higher proportions of full-time as compared with part-time staff psychiatrists were certified by the ABPN (table U).

In State mental hospitals only 19 percent of the FMG's and 43 percent of the AMG's were certified by the ABPN (NIMH May 1976).

EXPENDITURES

VOLUME OF EXPENDITURES

The dollar amount and percent distribution of expenditures in private psychiatric hospitals are shown by hospital control and size (based on number of beds) in table 11. The total expenditures in this table have been classified into more specific subcategories as follows:

1. Salaries of personnel,

- 2. Other operating expenses exclusive of salaries which include maintenance and other repair costs, and
- 3. Capital expenditures which include costs of construction of buildings, additions, and purchases of durable equipment.

Private psychiatric hospitals spent an estimated \$360.7 million during 1974. Of this amount,

^{1/} This table is based on 1,324 of the estimated 1,521 total psychiatrists and other physicians shown in table 5.

\$200.2 million (55.5 percent) were spent by not-for-profit hospitals and \$160.5 million (44.5 percent) by for-profit hospitals. Approximately 59 percent of total expenditures were allocated to salaries. In not-for-profit hospitals, 65 percent of total expenditures were allocated to salaries as compared with only 52 percent of total expenditures in for-profit hospitals. Within hospital control groups there was no discernible relationship between size of hospital and proportion of total expenditures allocated to salaries (table 11).

Other types of psychiatric hospitals exclusive of private psychiatric hospitals and the proportion of total expenditures allocated to salaries during 1974 were as follows: (1) State mental hospitals (80 percent) and (2) VA neuropsychiatric hospitals (76 percent).

EXPENDITURE INDICES

Average expenditures per private psychiatric hospital were \$2.0 million in 1974 or 37 percent higher than the average expenditures per hospital of \$1.5 million in 1969. Salary expenditures per hospital rose from \$.9 million in 1969 to \$1.2 million, an increase of 33 percent (table 12).

Average expenditures per not-for-profit hospital rose from \$1.9 million in 1969 to \$3.2 million in 1973, an increase of 67 percent. Much of the increase was attributed to salaries expenditures which increased 72 percent between 1969 and 1974.

Average total expenditures per not-for-profit hospital rose only 57 percent from \$.9 million in 1969 to \$1.4 million in 1974. Salary expenditures per for-profit hospital rose only 49 percent in the same time interval. However, it should be noted that these data reflect hospital expenditures, not costs to the patient. A larger proportion of psychiatrists and other physicians in for-profit as compared with not-for-profit hospitals have staff privileges and see patients in the hospital, but are not on the staff of the hospital and are not paid by the particular hospital (see page 8 and footnotes d and e). The average expenditures per patient day (the average amount spent to care for one inpatient for one day)h are shown by hospital control and

by size (based on number of beds) for 1969 and 1974 in table 13. The average expenditures per patient day were higher in not-for-profit than in for-profit mental hospitals with the differences accounted for largely by higher average salary expenditures. Once again these higher salary expenditure are attributed in large part to the larger proportion of "open staff" physicians in for-profit as compared with not-for-profit hospitals (see page 10 and footnotes d and e).

While the average expenditures per patient day in not-for-profit hospitals increased from \$52 in 1969 to \$96 in 1974 (85 percent), the average expenditures per patient day in for-profit hospitals increased from \$45 to \$74 (64 percent) in the same time interval. Here, again, the differences in the higher proportional increases in the expenditures per patient day in not-for-profit as compared with for-profit hospitals in the time interval 1969-74 are attributed to increases in salary expenditures in not-for-profit hospitals which nearly doubled as compared with only a 50 percent increase in the for-profit hospital expenditures per patient day (table 13).

Another expenditure index is the average expenditure per discontinuation, which is shown by size and by hospital control in table 14. Binner states that "as a program measure, the cost per patient discharged avoids some of the pitfalls inherent in the cost per patient day concept." It is (1) sensitive to patient turnover, (2) focuses on output rather than the cost of the process unit of treatment, and (3) avoids the spurious inflation of cost if a program manages to do its job more quickly or through the use of less intensive therapies (Binner).

The average expenditures per discontinuation were \$4,284 in not-for-profit hospitals as compared with \$2,215 in for-profit hospitals. The large difference in average expenditures per discontinuation between hospital control types is due primarily to the much lower average lengths

inpatient and other service modes while the denominator reflects the days for inpatient modes only. However, the expenditures in other service modes of private psychiatric hospitals are relatively small in comparison with the expenditures made in the provision of inpatient treatment. For this reason the index, although somewhat overstated, is reasonably accurate.

i The referenced paper by Paul R. Binner, Ph.D., presents a detailed discussion of some of the problems of interpreting cost-outcome measures such as costs per discharge and costs per patient day. It discusses cost-outcome measures much more extensively than could be covered in a statistical report such as this.

h The reader is cautioned that the average expenditures per patient day shown in this report are probably overestimated since the numerator reflects expenditures for services provided in

of stay in for-profit hospitals (32 days) as compared with not-for-profit hospitals (44 days) and to the employment of large proportions of non-salaried (open staff) physicians in for-profit hospitals, the latter of which results in costs billed to the patient, but not expenditures by the hospital.

The reader should be cautioned that on the basis of data presented in this report, inferences are unable to be made that lower expenditures per discontinuation in the for-profit hospitals imply more efficient operations. Factors such as differences in the age and diagnosis of patient groups served, differences in reimbursement agreements with third-party payors, hospital policies, and other factors influence the length of stay and ultimately contribute to the magnitude of the expenditures per discontinuation. Furthermore, there is no measure of the health of the patient following discontinuation and the benefits he or she may have derived from the particular hospitalization.

APPENDIX I. Differences in Lists of Private Psychiatric Hospitals Compiled by the National Institute of Mental Health (NIMH) and the National Association of Private Psychiatric Hospitals (NAPPH)

The NAPPH publishes a roster of its member hospitals, the latest of which is as of 1976. This list was compared with a list of private psychiatric hospitals compiled by NIMH as of May 1976. The results of the comparison which gives the number of hospitals included on the two lists on a State by State basis are given in Appendix table I.

A total of 179 hospitals were included on the NIMH list and 176 were included in the NAPPH list. A total of 152 hospitals (85 percent) were common to both lists.

Twenty-seven hospitals were on the NIMH list only. There are two probable reasons for this. First, the NIMH list was updated more recently and includes certain new hospitals that are not on the NAPPH list. Second, NIMH includes certain private psychiatric hospitals that are not members of the NAPPH.

Twenty-four hospitals appeared on the NAPPH list only (see Appendix table I). The reason for

j NAPPH Newsletter, Vol. XXV, No. 1, Section 2, 1976 k Because of differences in time period in which the lists were compiled, the number of hospitals reported in Appendix table I will differ slightly from the number included in other tables of this report.

this is that NIMH classifies these facilities not as private psychiatric hospitals but as other types of facilities as follows:

- a. Nine hospitals were classified as psychiatric units of general hospitals.
- b. Six hospitals were classified as federally assisted community mental health centers (CMHC's). Any private hospital which has received Federal monies under the CMHC Act and for which all the patients are considered CMHC patients is classified as a CMHC by NIMH.
- c. Six hospitals were classified as residential treatment centers for emotionally disturbed children (RTC's). In distinguishing between RTC's and hospitals, NIMH counts as hospitals only those facilities which are licensed as hospitals.
- d. Three hospitals which are solely or primarily for the treatment of alcohol and drug dependency patients are excluded from the NIMH lists since these facility types are outside the scope of the surveys which NIMH conducts.

APPENDIX II. Definition of Terms

A. CLASSIFICATION OF PRIVATE PSYCHIATRIC HOSPITALS

Private psychiatric hospitals — Hospitals operated privately by individuals, partnerships, corporations, or nonprofit organizations, primarily for the care of the mentally ill.

Not-for-profit hospitals — Private psychiatric hospitals controlled by foundations, churches, and other nonprofit groups.

For-profit hospitals — Private psychiatric hospitals controlled by corporations, partnerships, or individuals operating on a for-profit basis.

Beds — Number of inpatient beds set up and staffed for use as of December 31, 1974.

Bed size — The number of inpatient beds in a given hospital set up and staffed for use as of December 31, 1974.

Geographic region — For the purpose of classifying private psychiatric hospitals by geographic area, the States are grouped into the 10 geographic regions which are used by the DHEW. The States included in each region are shown in table 1.

B. TYPES OF SERVICE MODES

- a. Inpatient treatment Provision of mental health treatment to persons requiring 24-hour supervision.
- b. Outpatient treatment Provision of mental health treatment on an outpatient basis to persons who do not require either full-time or partial hospitalization.
- c. Day treatment Provision of planned therapeutic services during most or all of the day to persons who need broader programs than are possible through outpatient visits.
- d. Other partial hospitalization Provision of planned therapeutic services during the evening, night, or weekend to persons who do not require full-time hospitalization but who need broader services than are possible through outpatient visits.
- e. Halfway House Provision of services which prepare a previously hospitalized patient for return to home and community environment by providing transitional living quarters and assistance in the activities of daily living or to prevent possible hospitalization.
- f. Emergency services Services (exclusive of those providing only holding beds and those primarily for drug and alcohol abuse) to provide psychiatric care in emergency situations by staff specifically assigned for this purpose.

C. PATIENT MOVEMENT – INPATIENT SERVICE MODES

a. Inpatients at beginning of year — Includes all persons who were physically present for 24 hours in the inpatient service at the beginning of the

year, or who were away on short visits as long as they were expected to return to the inpatient service, or who were on unauthorized absence, AWOL or escape.

- b. Additions during year Includes admissions and readmissions as well as returns from long-term leave and transfers from noninpatient components of the same hospital.
- c. Deaths in hospital during year Includes those persons who died while under inpatient care or while away on short visits.
- d. Discontinuations during year Includes persons discharged (including deaths) as well as those placed on long-term leave and transferred to non-inpatient components of the same hospital.
- e. Inpatients at end of year Includes all persons who were physically present for 24 hours in the inpatient service at the end of the year, or who were away on short visits as long as they were expected to return to the inpatient service, or who were on unauthorized absence, AWOL or escape.
- f. Patient care episodes Patient care episodes are defined as the number of inpatients in private psychiatric hospitals at the beginning of the year (or the number of persons on the rolls of noninpatient facilities) plus the total additions to these facilities during the year. Total additions during the year include new admissions, readmissions, and returns from leave. It is, therefore, a duplicated count of persons. In counting additions rather than persons, two types of duplication are introduced. First, the same persons may be admitted more than once to a particular facility during the year. In this case the same person is counted as many times as he is admitted. Secondly, the same person may be admitted to two or more different facilities during the year. Again he is counted as an admission for each facility to which he is admitted. Duplication also occurs because episodes are counted independently by modality (inpatient, outpatient, day treatment services). A person who is an inpatient in a hospital, released to a day care program and then followed as an outpatient, for example, would be counted as having three episodes.

D. ADDITIONS-NONINPATIENT SERVICE MODES

- a. Additions-outpatient service Persons admitted or readmitted to this service mode or transferred to this service mode from another service mode of this hospital during the year.
- b. Additions-day treatment service See definition for "Additions-outpatient service."
- c. Additions-Halfway House service See definition for "Additions-outpatient service."

E. UTILIZATION INDICES

- a. Average daily census (ADC) The average daily number of inpatients which is the total annual inpatient days divided by the number of days in a year (365 in 1974).
- b. Average daily census per hospital The average daily census (see above definition) for a particular group of hospitals (e.g., hospitals 50-99 beds) divided by the number of hospitals in that group.
- c. Additions per 100 average daily inpatients The number of annual additions (see definition under "Patient movement") per 100 average daily census (see definition above).

- d. Discontinuations per 100 average daily inpatients The number of annual discontinuations (see definition under "Patient movement") per 100 average daily census (see definition above).
- e. Additions per 100,000 population The number of inpatient additions (see definition under "Patient movement") per 100,000 persons in the civilian resident population at midyear 1974.
- f. Average length of stay The average daily census x 365 divided by the average discontinuations.

F. STAFFING

- a. Full-time employees Persons employed 35 or more hours a week (excluding trainees). Schoolteachers are counted as full time if they are employed 30 hours or more a week.
- b. Part-time employees Persons employed less than 35 hours a week (excluding trainees).
- c. Trainees Trainees including residents and interns, regardless of the number of hours worked in a week.
- d. Patient care staff All employees excluding administrative and maintenance employees (see definition which follows).
- e. Professional patient care staff Includes psychiatrists, nonpsychiatric physicians, psychologists, social workers, registered nurses, other mental health professionals (e.g., occupational therapists, vocational rehabilitation counselors, and other mental health professionals requiring BA level training), and other health professionals (e.g., dieticians, dentists, dental technicians, and pharmacists).
- f. Other patient care staff Includes licensed practical and vocational nurses, mental health workers with an AA degree or higher, but less than a BA degree, and mental health workers with less than an AA degree.
- g. Administrative and maintenance staff Includes administrative and other professional (nonhealth) staff (e.g., accountants, business administrator) as well as clerical and maintenance staff.
 - h. Staff hour A unit of 1 hour's work by one employee.
- i. Full-time equivalents The total person hours worked by full-time employees, part-time employees, and trainees in each staff discipline divided by 40 hours to indicate the number of persons working a 40-hour week to provide this many person hours.

APPENDIX III. Extent of Nonresponse and Estimation Procedures

All frequencies shown in the tables in this report are based either on information available for all hospitals or have been adjusted to include estimates for private psychiatric hospitals which either did not respond to the survey or did not report specific items. The decision to adjust the data was based on the high response rate to all items on the Inventory form which ranged from 74 percent of the hospitals which reported information on expenditures to 93 percent of the hospitals which reported types of service.

The adjustments were made on the assumption that characteristics of nonrespondents within each of the size (based on number of beds) groups, geographic region, and hospital control were similar to the hospitals within

these groups which responded.

Certain indices such as total expenditures per patient day which require different types of data in the numerator and denominator are based on reported data only to ensure that the data in the numerator and denominator are reported by the same hospitals.

Only 13 hospitals (7.2 percent) did not submit an Inventory. However the geographic region of all 180 private mental hospitals was known on an a priori basis. Data were also available from all hospitals on the number of beds because, for hospitals that did not respond, information was obtained from AHA Guide Issue.

Although the response rate for most items was relatively high, there were variations in the proportion of hospitals which reported certain items. Appendix table II shows the response rate of private mental hospitals with regard to specific items in the tables.

Appendix Table II. Rate of response of private psychiatric hospitals to specific items on the 1974 Inventory of Mental Health Facilities

| | | Number of | Response | | |
|----------------------------------|-------------------|--------------------|---------------------|---------|--|

DETAILED TABLES

| Table | | Page |
|-------|--|------|
| 1. | Number of beds, number of additions and number of persons receiving care at end of year, inpatient service modes of private psychiatric hospitals: United States, 1974 | 31 |
| 2. | Number and percent of private psychiatric hospitals maintaining specified service modes by hospital control and size (based on number of beds): United States, January 1975 | 33 |
| 3. | Percent of private psychiatric hospitals specifying restrictions with regard to the admission of certain diagnostic groups for selected service modes, by hospital control: United States, January 1975 | 34 |
| 4. | Percent distribution of hospitals by age groups accepted for admission, private psychiatric hospitals, in type of service mode and hospital control: United States, January 1975 | 34 |
| 5. | Number of positions and staff hours worked in a sample week by discipline and training of staff, private psychiatric hospitals: United States, January 1975 | 35 |
| 6. | Percent distribution by status for number of positions and staff hours worked in a sample week according to staff discipline and training of staff, private psychiatric hospitals: United States, January 1975 | 36 |
| 7. | Percent distribution by staff discipline and training for number of positions and staff hours worked in a sample week according to status, private psychiatric hospitals: United States, January 1975 | 37 |
| 8. | Number and percent distribution of full-time equivalent staff, private psychiatric hospitals, by staff discipline, hospital control and size (based on number of beds): United States, January 1975 | 38 |
| 9. | Percent distribution of American (including Canadian) and foreign medical graduates employed in private psychiatric hospitals by age, by sex, and by whether U.S. citizen: United States, January 1975 | 39 |
| 10. | Number and percent of foreign medical graduates employed in private psychiatric hospitals who have passed ECFMG by type of position and full- or part-time status: United States, January 1975 | 40 |
| 11. | Number and percent distribution of expenditures in private psychiatric hospitals by type of expenditure, by hospital control and size (based on number of heds): United States, 1974 | 41 |

| able | | Page |
|------|--|------|
| 12. | Average expenditures per private psychiatric hospital by hospital control and size (based on number of beds): United States, 1969 and 1974 | 42 |
| 13. | Average expenditures per patient day in private psychiatric hospitals by hospital control and size (based on number of beds): United States, 1969 and 1974 | 43 |
| 14. | Average expenditures per discontinuation in private psychiatric hospitals by hospital control and size (based on number of beds): United States, 1974 | 44 |

^{1/} The data in this table have been adjusted to include estimates for private mental hospitals which did <u>not</u> respond to the January 1975 Inventory of Mental Health Facilities conducted by the National Institute of Mental Health.

 $[\]underline{2}$ / The number of beds for hospitals that did not respond to the Inventory was obtained as of 9/30/74 from the AHA Guide Issue.

^{3/} For Vermont the average daily census as of 9/30/74 obtained from AHA Guide Issue was used in place of the number of resident patients at end of 1974.
